(Received 3 August 2005; revised manuscript received 8 November 2005; published 18 January 2006)

We reconsider density matrices of graphs as defined in quant-ph/0406165. The density matrix of a graph is the combinatorial Laplacian of the graph normalized to have unit trace. We describe a simple combinatorial condition (the “degree condition”) to test the separability of density matrices of graphs. This condition is directly related to the Peres-Horodecki partial transposition condition. We prove that the degree condition is necessary for separability, and we conjecture that it is also sufficient. We prove special cases of the conjecture involving nearest-point graphs and perfect matchings. We observe that the degree condition appears to have a value beyond the density matrices of graphs. In fact, we point out that circulant density matrices and other matrices constructed from graphs always satisfy the condition and indeed are separable with respect to any split. We isolate a number of problems and delineate further generalizations.

I. INTRODUCTION

Let us consider the set $S$ of all density matrices $\rho$ of a bipartite system with assigned Hilbert space $\mathbb{C}^q \otimes \mathbb{C}^p$. Let $\mathcal{M}(pq)$ be the linear space (over the complex field $\mathbb{C}$) of all $pq \times pq$ complex matrices equipped with the inner product $\langle A|B \rangle := \text{Tr}(A^*B)$ for any $A, B \in \mathcal{M}(pq)$. Let us consider the metric $D(A,B) := \langle (A-B)|(A-B) \rangle$ on $\mathcal{M}(pq)$, for any $A, B \in \mathcal{M}(pq)$. With respect to this metric, the set $S$ forms a compact (which is also convex) subset of $\mathcal{M}(pq)$ generated by $(p^2q^2-1)$ real parameters. Deciding whether a given element from this compact set $S$ is separable or entangled (the separability problem) is known to be NP hard [18] (see also [1]). This problem is an instance of the weak membership problem as defined by Grötschel et al. [2] (see also [3]). Recently the separability problem has been considered and discussed in [1,4–6].

There are few cases where the separability problem is known to be efficiently solvable. The best known situation is $(p,q)=(2,3)$ or $(3, 2)$. In this case, the positivity of $\rho^\dagger \rho$ (the partial transposition of $\rho$ with respect to the system $B$) is equivalent to the separability of $\rho$ [7,8]. Also, the set of all density matrices “very near” (in the sense of some useful metric) to the maximally mixed state is known to be separable [9]. Other examples are given in [10].

For some discrete family of density matrices (that is, for which no continuity argument can be applied), no such efficient criterion is known to us. Here we consider the family of the density matrices of graphs as introduced in [11]. In the remainder of this section we introduce some terminology and state the results. There are two other sections in the paper: Section II contains the proofs. Section III is a list of further problems and generalizations.

Let $G=(V,E)$ be a simple graph on $n$ labeled vertices—that is, $V=\{v_1,v_2,\ldots,v_n\}$ and $E \subseteq V^2 = \{(v_i,v_j): v_i,v_j \in V \text{ and } i \neq j\}$. The adjacency matrix of $G$ is an $n \times n$ matrix, denoted by $M(G)$, with lines indexed by the vertices of $G$ and $ij$th entry defined as $[M(G)]_{ij} = 1,$ if $\{v_i,v_j\} \in E(G),$ 

$0,$ if $\{v_i,v_j\} \notin E(G).$

The degree matrix of $G$ is an $n \times n$ matrix, denoted by $\Delta(G)$, with $ij$th entry defined as $[\Delta(G)]_{ij} = |\{v_j: \{v_i,v_j\} \in E\}|,$ if $i = j,$ 

$0,$ if $i \neq j.$

The Laplacian [12] of $G$ is the symmetric positive semidefinite matrix

$L(G) := \Delta(G) - M(G).$

Other than this combinatorial Laplacian, there are several other types of Laplacians associated with graphs [13]. The matrix

$\rho(G) = \frac{1}{2|E|}L(G)$

is a density matrix. This is called the density matrix of $G$ [11].

It should be noted here that the notion of density matrix $\rho(G)$ of a graph $G=(V(G),E(G))$, as defined above, is completely different from the notion of “graph states,” introduced by Briegel and Raussendorf [14]. A graph state $|G\rangle$, corresponding to a (simple) graph $G=(V(G),E(G))$, is a common eigenstate (corresponding to the eigenvalue 1) of the $n=|V(G)|$ number of n-qubit operators $\sigma_1 \otimes \sigma_2 \otimes \cdots \otimes \sigma_n$, $\sigma_{21} \otimes \sigma_{22} \otimes \cdots \otimes \sigma_{2n}$, $\sigma_{31} \otimes \sigma_{32} \otimes \cdots \otimes \sigma_{3n}$, where (i) $\sigma_{ij} = \sigma_i$ for all $i \in \{1,2,\ldots,n\}$, (ii) for $j \neq i$, $\sigma_{ij}=\sigma_j$, if the vertices $v_i$ and $v_j$ of $G$ are connected by an edge, and (iii) for $j \neq i$, $\sigma_{ij}=I$ if the vertices $v_i$ and $v_j$ of $G$ are not connected by an edge. Thus, in this formalism, a two-level system is attached with each vertex of the graph and each edge of the graph represents an interaction (Ising type) between the two two-level subsystems attached to the two vertices of the edge.

Let $G$ be a graph on $n=p \cdot q$ vertices $v_1, v_2, \ldots, v_n$. These vertices are represented here as ordered pairs in the follow-
ing way: \( v_1 = (u_1, w_1) = u_1 w_1, v_2 = (u_1, w_2) = u_1 w_2, \ldots, v_p = (u_1, \ldots, u_p, w_q) = u_1 w_q, \) \( v_{q+1} = (u_2, w_1) = u_2 w_1, v_{q+2} = (u_2, w_2) = u_2 w_2, \ldots, v_{(p-1)q+1} = (u_p, w_1) = u_p w_1, \) \( v_{(p-1)q+2} = (u_p, w_2) = u_p w_2, \ldots, v_{pq} = (u_p, \ldots, u_q) = u_p w_q. \)

We associate to this graph \( G \) on \( n \) labeled vertices (described above) the orthonormal basis \( \{v_i\}_{i=1,2,\ldots,n} = \{(u_j) \otimes (w_j) : j = 1,2,\ldots,p \} \), where \( \{w_j\} : k = 1,2,\ldots,q \) are orthonormal bases of the Hilbert spaces \( \mathcal{H}_A \cong \mathbb{C}^p \) and \( \mathcal{H}_B \cong \mathbb{C}^q \), respectively. The partial transpose of a graph \( G = (V,E) \) (with respect to \( \mathcal{H}_B \)), denoted by \( G^T_B = (V,E') \), is the graph such that \( \{u_i w_{k_i} : k_i = 1,2,\ldots,q \} \) is a unique vertex \( v_j \) such that \( \{v_i, v_j\} \in E \).

**Conjecture 1.** Let \( \rho(G) \) be the density matrix of a graph on \( n = pq \) vertices. Then \( \rho(G) \) is separable in \( C_A^p \otimes C_B^q \) if and only if \( \Delta(G) = \Delta(G^{T_B}) \).

A proof of this conjecture would give a simple method for testing the separability of density matrices of graphs, as we would only need to check whether the \( n \times n \) diagonal matrices \( \Delta(G) \) and \( \Delta(G^{T_B}) \) are equal. This fact is in some sense analogous to the fact that the separability of all two-mode Gaussian states (which form a continuous family) is equivalent to the Peres-Horodecki partial transposition criterion [15]. We prove one side of our conjecture.

**Theorem 2.** Let \( \rho(G) \) be the density matrix of a graph on \( n = pq \) vertices. If \( \rho(G) \) is separable in \( C_A^p \otimes C_B^q \), then \( \Delta(G) = \Delta(G^{T_B}) \).

We prove the other side of the conjecture for the following two families of graphs.

(i) Consider a rectangular lattice with \( pq \) points arranged in \( p \) rows and \( q \) columns, such that the distance between two neighboring points on the same row or in the same column is 1. A **nearest-point graph** is a graph whose vertices are identified with the points of the lattice and the edges have length 1 or \( \sqrt{2} \).

(ii) A **perfect matching** is a graph \( G = (V,E) \) such that for every \( v_i \) there is a unique vertex \( v_j \) such that \( \{v_i, v_j\} \in E \).

Namely, we prove the following two theorems.

**Theorem 3.** Let \( G \) be a nearest point graph on \( n = pq \) vertices. Then the density matrix \( \rho(G) \) is separable in \( C_A^p \otimes C_B^q \) iff \( \Delta(G) = \Delta(G^{T_B}) \).

**Theorem 4.** Let \( G \) be a perfect matching on \( n = 2k \) vertices. Then the density matrix \( \rho(G) \) is separable in \( C_A^k \otimes C_B^k \) iff \( \Delta(G) = \Delta(G^{T_B}) \).

See Fig. 1 as examples of perfect matching \( H \), the partial transpose graph \( H^{T_B} \), nearest-point graph \( G \), and the partial transpose graph \( G^{T_B} \).

The **degree condition** expressed in the conjecture appears to have value beyond density matrices of graphs. In general, given a density matrix \( \rho \) in \( C_A^p \otimes C_B^q \), let \( \Delta(\rho) \) be the matrix defined as follows:

\[
[\Delta(\rho)]_{ij} = \begin{cases} 
   \sum_{k=1}^{pq} \rho_{ik}, & \text{if } i = j, \\
   0, & \text{if } i \neq j.
\end{cases}
\]

In a **circulant matrix** each row is a cyclic shift of the row above to the right. This means that a circulant matrix is then defined by its first row. Let \( G \) be a finite group of order \( n \), and let \( \sigma \) be the regular permutation representation of \( G \). Then \( \sigma \) is an homomorphism from \( G \) to the set of permutation matrices of dimension \( n \). The **Fourier transform** (evaluated at \( \sigma \)) of a complex-valued function \( f \) on \( G \) is defined as the matrix \( f = \Sigma f(\sigma) \sigma(\sigma) \) [16]. According to this definition, a complex circulant matrix \( M \) of dimension \( n \) has the form \( M = \Sigma_{k=1}^n f(\sigma) \sigma(\sigma) \). We prove the following result.

**Theorem 5.** Let \( \rho \) be a circular density matrix of dimension \( n = pq \). Then \( \Delta(\rho) = \Delta(\rho^{T_B}) \) and \( \rho \) is separable in \( C_A^p \otimes C_B^q \). Let \( \rho = \Sigma_{k=1}^{pq} f(\sigma) \sigma(\sigma) \) be a density matrix of dimension \( n^2 \). Then \( \Delta(\rho) = \Delta(\rho^{T_B}) \) and \( \rho \) is separable in \( C_A^k \otimes C_B^k \), where \( k+l=n \).

**II. PROOFS**

**A. Proof of theorem 2**

Let \( L(G) \) be the Laplacian of a graph \( G = (V,E) \) on \( n \) vertices \( v_1, \ldots, v_n \). Let \( D \) be any \( n \times n \) real diagonal matrix in the orthonormal basis \( \{|v_i\}, \ldots, |v_n\} \) such that \( D \neq 0 \) and \( tr(D) = 0 \). It follows that there is at least one negative entry in the diagonal of \( D \). Let this entry be \( D_{i,i} = b_i \). Let \( |\psi_0\rangle = \sum_{i=1}^n |v_i\rangle \) and \( |\phi\rangle = \sum_{i=1}^n \chi_i |v_i\rangle \), where

\[
\chi_i = \begin{cases} 
   0, & \text{if } j \neq i, \\
   k & \text{if } j = 1.
\end{cases}
\]

Let \( |\chi\rangle = |\psi_0\rangle + |\phi\rangle = \sum_{i=1}^n (1 + \chi_i) |v_i\rangle \). Then,

\[
\langle \chi | (L(G) + D) | \chi \rangle = \langle \chi | L(G) | \chi \rangle + \langle \chi | D | \chi \rangle
\]

\[
= \langle \psi_0 | L(G) | \psi_0 \rangle + \langle \psi_0 | L(G) | \phi \rangle + \langle \phi | L(G) \rangle
\]

\[
\times |\psi_0\rangle + (\phi | L(G) \rangle \phi + (\psi_0 | D | \phi) + (\phi | D | \psi_0) + (\phi \langle D | \phi) + (\phi \langle D | \psi_0) + (\phi \langle D | \phi) + (\phi \langle D | \phi).
\]

The state \( |\psi_0\rangle \) is an eigenvector (unnormalized) of \( L(G) \), corresponding to the eigenvalue 0: \( L(G) |\psi_0\rangle = 0 \). Also \( \langle \psi_0 | D | \phi \rangle = tr(D) = 0 \). Then,
\[
\langle \chi \vert (L(G) + D) \vert \chi \rangle = \langle \psi_0 \vert L(G) \vert \phi \rangle + \langle \phi \vert L(G) \vert \phi \rangle + \langle \psi_0 \vert D \vert \phi \rangle + \langle \phi \vert D \vert \phi \rangle.
\]

Now \( \langle \psi_0 \vert L(G) \vert \phi \rangle = \langle \phi \vert L(G) \vert \phi \rangle = \langle \phi \vert L(G) \vert \psi_0 \rangle = 0 \). In fact, \( L(G) = L(G)^T \). Let \([L(G)]_{ji} \) be the \( j \)th entry of \( L(G) \) with respect to the basis \( \{ \vert v_j \rangle : j \in E \} \). We have
\[
\langle \phi \vert L(G) \vert \phi \rangle = k^2 (L(G))_{ji} = k^2 d_i,
\]
\[
\langle \phi \vert D \vert \phi \rangle = b_i k^2,
\]
\[
\langle \psi_0 \vert D \vert \phi \rangle = b_i k,
\]
\[
\langle \phi \vert D \vert \psi_0 \rangle = b_j k.
\]

Thus,
\[
\langle \chi \vert (L(G) + D) \vert \chi \rangle = k^2 (d_i + b_i) + 2b_k,
\]
with \( d_i \geq 0 \) and \( b_i < 0 \).

So we can then always choose a positive \( k \), small enough, such that
\[
2b_k + k^2 (d_i + b_i) < 0.
\]

It follows that
\[
L(G) + D \neq 0.
\]

For any graph \( G \) on \( n \) vertices,
\[
v_1 = (u_1, w_1), v_2 = (u_1, w_2), \ldots, v_q = (u_1, w_q), v_{q+1} = (u_2, w_1), v_{q+2} = (u_2, w_2), \ldots, v_{2q} = (u_2, w_q), \ldots, v_{pq} = (u_p, w_q),
\]
consider now the degree condition \( \Delta(G) = \Delta(G^{T}) \). Now,
\[
(L(G))^T = [\Delta(G) - \Delta(G^{T})] + L(G^{T}).
\]

Let
\[
D = \Delta(G) - \Delta(G^{T}).
\]

Then \( D \) is an \( n \times n \) real diagonal matrix with respect to the orthonormal basis
\[
|v_j \rangle = |u_1 \rangle \otimes |w_j \rangle, \ldots, |v_{pq} \rangle = |u_p \rangle \otimes |w_q \rangle.
\]

Also,
\[
\text{tr}(D) = \text{tr}[\Delta(G)] - \text{tr}[\Delta(G^{T})] = 0.
\]

As \( G^{T}_n \) is a graph on \( n \) vertices \( v_1, v_2, \ldots, v_n \), as here \( D = \Delta(G) - \Delta(G^{T}) \) is a diagonal matrix with respect to the orthonormal basis \( \{ |v_1 \rangle, |v_2 \rangle, \ldots, |v_n \rangle \} \), and as here \( \text{tr}(D) = 0 \), therefore, by the above-mentioned reasoning, \( D + L(G^{T}) \neq 0 \) if \( D \neq 0 \). Now if \( \rho(G) \) is separable then we must have \( L(G)^{T} = (D + L(G^{T})) \geq 0 \) [8]. Therefore separability of \( L(G) \) implies that \( D = \Delta(G) - \Delta(G^{T}) = 0 \).

**B. Proof of theorem 3**

Let \( G \) be a nearest-point graph on \( n = pq \) vertices and \( m \) edges. We associate to \( G \) the orthonormal basis \( \{ |u_j \rangle : j = 1, 2, \ldots, n \} \), \( \{ |w_k \rangle : k = 1, 2, \ldots, q \} \), where \( \{ |u_j \rangle : j = 1, 2, \ldots, p \} \) is an orthonormal basis of \( G^{T}_n \) and \( \{ |w_k \rangle : k = 1, 2, \ldots, q \} \) is an orthonormal basis of \( G^{T}_p \). Let \( j, j' \in \{ 1, 2, \ldots, p \} \) and \( k, k' \in \{ 1, 2, \ldots, q \} \). Let \( \lambda_{jk, j'k'} \in \{ 0, 1 \} \) be defined as follows:

\[
\lambda_{jk, j'k'} = \begin{cases} 
1, & \text{if } \{ |u_j w_{k'} \rangle, |u_{j'} w_k \rangle \} \in E, \\
0, & \text{if } \{ |u_j w_{k'} \rangle, |u_{j'} w_k \rangle \} \notin E.
\end{cases}
\]

Thus, for the above-mentioned nearest-point graph \( G \), \( \lambda_{jk, j'k'} \) can have nonzero values only in the following cases: either (i) \( j' = j \) and \( k' = k + 1 \), (ii) \( j' = j + 1 \) and \( k' = k \), (iii) \( j' = j + 1 \) and \( k' = k + 1 \), or (iv) a combination of some or all three cases (i)–(iii). Let \( \rho(G) \) and \( \rho(G^{T}) \) be the density matrices corresponding to the graphs \( G \) and \( G^{T} \), respectively. Thus,

\[
\rho(G) = \frac{1}{2m} [\Delta(G) - M(G)],
\]
\[
\rho(G^{T}) = \frac{1}{2m} [\Delta(G^{T}) - M(G^{T})].
\]

Let \( G_1 \) be the subgraph of \( G \) whose edges are all the entangled edges of \( G \). An edge \( \{ij, kl\} \) is entangled if \( i \neq k \) and \( j \neq l \). Also let \( G'_1 \) be the subgraph of \( G^{T} \) corresponding to all the “entangled edges” of \( G^{T} \). Obviously \( G'_1 = (G_1)^{T} \). Using the above-mentioned notations, we have

\[
\rho(G_1) = \frac{1}{m} \sum_{p} \left( \lambda_{(j-1)l, (j'k-1)l} P \left[ \frac{1}{\sqrt{2}} (|u_{j-1} w_{k-1} \rangle - |u_{j-1} w_{k} \rangle) \right] \right) + \frac{1}{m} \sum_{p} \left( \lambda_{(j-1)l, (j'k-1)l} P \left[ \frac{1}{\sqrt{2}} (|u_{j-1} w_{k-2} \rangle - |u_{j-1} w_{k-1} \rangle) \right] \right).
\]

\[
+ \lambda_{(j-1)l, j'k} P \left[ \frac{1}{\sqrt{2}} (|u_{j-1} w_{k-1} \rangle - |u_{j-1} w_{k} \rangle) \right] + \frac{1}{m} \sum_{p} \left( \lambda_{(j-1)l, j'k} P \left[ \frac{1}{\sqrt{2}} (|u_{j-1} w_{k-1} \rangle - |u_{j-1} w_{k} \rangle) \right] \right),
\]

where, for any normalized pure state \( |\psi \rangle \), \( P[|\psi \rangle] \) denotes the one-dimensional projector onto the vector \( |\psi \rangle \). Also we have
\[
\rho(G') = \frac{1}{m} \sum_{j=2}^{p} \left( \lambda_{(j-1),j} P \left[ \frac{1}{\sqrt{2}} (|u_{(j-1)j}w_{2} - |u_{j}w_{1}|) \right] \right) + \frac{1}{m} \sum_{j=3}^{q} \left( \lambda_{(j-1)(k-2),j} P \left[ \frac{1}{\sqrt{2}} (|u_{(j-1)(k-2)}w_{2} - |u_{j}w_{k-1}|) \right] \right) \\
+ \lambda_{(j-1)(k-1),j} P \left[ \frac{1}{\sqrt{2}} (|u_{j}w_{k} - |u_{j}w_{k-1}|) \right] + \frac{1}{m} \sum_{j=2}^{p} \left( \lambda_{(j-1)q,q(j-1)} P \left[ \frac{1}{\sqrt{2}} (|u_{j}w_{q-1} - |u_{j}w_{q}|) \right] \right).
\]

One can check that
\[
\Delta(G_1) = \frac{1}{2m} \left( \lambda_{11,22} P[|u_{1}w_{1}|] + \sum_{k=3}^{q} (\lambda_{1(k-2),2(k-1)} + \lambda_{1k,2(k-1)}) P[|u_{1}w_{k-1}|] + \lambda_{1q,2(q-1)} P[|u_{1}w_{q}|] \right) + \frac{1}{2m} \sum_{j=3}^{q} (\lambda_{(j-2)1,1(j-1)2} \\
+ \lambda_{(j-2)1,1(j-1)k}) P[|u_{j}w_{k-1}|] + \frac{1}{2m} \sum_{k=3}^{q} (\lambda_{(j-2)q,1(q-1)} P[|u_{j}w_{q-1}|] + \lambda_{1q,2(q-1)} P[|u_{1}w_{q}|]) + \frac{1}{2m} \sum_{k=3}^{q} (\lambda_{(j-2)q,1(q-1)} P[|u_{j}w_{q-1}|] + \lambda_{1q,2(q-1)} P[|u_{1}w_{q}|]).
\]

and
\[
\Delta(G'_1) = \frac{1}{2m} \left( \lambda_{12,21} P[|u_{1}w_{1}|] + \sum_{k=3}^{q} (\lambda_{1(k-2),2(k-1)} + \lambda_{1k,2(k-1)}) P[|u_{1}w_{k-1}|] + \lambda_{1q,2(q-1)} P[|u_{1}w_{q}|] \right) + \frac{1}{2m} \sum_{j=3}^{q} (\lambda_{(j-2)1,1(j-1)2} \\
+ \lambda_{(j-2)1,1(j-1)k}) P[|u_{j}w_{k-1}|] + \frac{1}{2m} \sum_{k=3}^{q} (\lambda_{(j-2)q,1(q-1)} P[|u_{j}w_{q-1}|] + \lambda_{1q,2(q-1)} P[|u_{1}w_{q}|]) + \frac{1}{2m} \sum_{k=3}^{q} (\lambda_{(j-2)q,1(q-1)} P[|u_{j}w_{q-1}|] + \lambda_{1q,2(q-1)} P[|u_{1}w_{q}|]).
\]

Let \(G_2\) and \(G'_2\), respectively, be the subgraphs of \(G\) and \(G'^{\prime}\), each containing all the edges of the forms \(\{u_{i}w_{j}, u_{i}w_{j'}\}\) (where \(j \neq j'\)) as well as \(\{u_{i}w_{j}, u_{i}w_{j'}\}\) (where \(i \neq i'\)). Then it is obvious that \(\Delta(G_2) = \Delta(G'_2)\), due to the fact that \(G_2\) and \(G'_2\) represent the same graph. So \(\Delta(G) = \Delta(G'^{\prime})\) if and only if \(\Delta(G_1) = \Delta(G'_1)\). Using Eqs. (2.4) and (2.5), we see that the equality of \(\Delta(G_1)\) and \(\Delta(G'_1)\) implies that
\[
\lambda_{11,22} = \lambda_{12,21},
\]
\[
\lambda_{1k,2(k-2)} + \lambda_{1(k-2),2(k-1)} + \lambda_{1k,2(k-1)},
\]
for \(k = 3, 4, \ldots, q\),
\[
\lambda_{1q,2(q-1)} = \lambda_{1(q-1),2q},
\]
for each \(j \in \{3, 4, 44, \ldots, p\}\),
\[
\lambda_{(j-1)(k-1),j} + \lambda_{(j-1)j,2} = \lambda_{(j-2)1,1(j-1)2} + \lambda_{(j-1)j,2},
\]
\[
\lambda_{(j-1)q,q(j-1)} + \lambda_{(j-1)q,q(j-1)} + \lambda_{(j-1)(q-1),jq},
\]
(2.6)
\[
\lambda_{(p-1)1,2,2p-2} = \lambda_{(p-1)2,2p-1},
\]
\[
\lambda_{(p-1)(k-2),p(k-1)} = \lambda_{(p-1)(k-1),p(k-1)} + \lambda_{(p-1)(k-1),p(k-1)},
\]
for \(k = 3, 4, \ldots, q\),
\[
\lambda_{(p-1)(q-1),pq} = \lambda_{(p-1)q,p(q-1)}.
\]

The solution of Eqs. (2.6)–(2.8) is of the form
Some Families of Density Matrices for Which...

\[ \lambda_{ij,i'} = \lambda_{ij,i'} \quad \text{for all } i,i' \in \{1,2,\ldots,p\} \]

and wherever \( \lambda_{ij,i'} \) and \( \lambda_{ij,i'} \) are defined. Equation (2.9) shows that whenever there is an entangled edge \( \{u_iw_j,u_iw_j'\} \) in \( G \) (so we must have \( i \neq i' \) and \( j \neq j' \)), there must be the entangled edge \( \{w_ju_i, w_j'u_i\} \) in \( G \). The two entangled edges \( \{u_iw_j, u_iw_j'\} \) and \( \{u_iw_j', u_iw_j\} \) in \( G \) together give rise to the following contribution (which is again a density matrix) in the density matrix \( \rho(G) \), with the multiplicative factor 2/\( m \):

\[
\rho(i,i':j,j') = \frac{1}{2} \left[ \frac{1}{\sqrt{2}} \left( |u_iw_j| - |u_iw_j'| \right) \right] + \frac{1}{2} \left[ \frac{1}{\sqrt{2}} (|w_j| - |w_j'|) \right].
\]

Let us write

\[
\frac{1}{\sqrt{2}} (|u_i| \pm |u_j|) = |V(i,i'; \pm)|, \quad \frac{1}{\sqrt{2}} (|w_j| \pm |w_j'|) = |X(j,j'; \pm)|.
\]

Using Eq. (2.11), it is easy to see from Eq. (2.10) that

\[
\rho(i,i':j,j') = \frac{1}{2} \left[ \frac{1}{\sqrt{2}} |u_iw_j| - |u_iw_j'| \right] + \frac{1}{2} \left[ \frac{1}{\sqrt{2}} |w_j| - |w_j'| \right] = \rho(i,i';j,j').
\]

which is a separable state in \( C_G^2 \otimes C_B^2 \). This shows that, under the constraint \( \Delta(G_1) = \Delta(G'_1) \), \( \rho(G_2) \) is nothing but an equal mixture of separable states of the form \( \rho(i,i';j,j') \), and so \( \rho(G) \) must be separable, which, in turn, shows that \( \rho(G) \) has to be separable. This shows that a nearest-point graph \( G \) is separable in \( C_G^2 \otimes C_B^2 \) if and only if \( \Delta(G) = \Delta(G^S) \).

C. Perfect matchings

1. Proof of theorem 4

Definition (degree condition). For any graph \( G \) on \( n=pq \) vertices \( v_1 = (u_1,w_1), \ldots, v_n = (u_n,w_n) \), the equation

\[
\Delta(G) = \Delta(G^S) \text{ is called the degree condition,}
\]

where \( G^S \) is the graph with \( V(G^S) = V(G) \) and \( \{u_i,w_j\}, \{u_i,w_j\} \in E(G^S) \) if and only if \( \{u_i,w_j\}, \{u_i,w_j\} \in E(G) \).

We consider here only those graphs \( G \) on \( n=pq \) vertices, where \( n \) is even and \( E(G) \) consists of edges of the forms \( \{(i,j),(i,j')\} \), where \( i \) runs from 1 to \( n/2 \), (ii) \( (i,j),(i',j') \) for all \( k \), (iii) \( (i,j),(i',j') \) whenever \( k \neq k' \), (iv) \( (i,j),(i',j') \) whenever \( k \neq k' \), and (v) \( (i,j),(i',j') \) whenever \( k \neq k' \) whenever \( k \neq k' \). Thus \( G \) is nothing but a perfect matching on \( n=pq \) vertices. In addition to above-mentioned conditions, if we have \( i_k \neq i_k' \) and \( j_k \neq j_k' \) for each \( k \in \{1,2,\ldots,n/2\} \), then \( G \) is called as a perfect entangling matching. We denote the set of all such perfect entangling matchings on the same set of \( n=pq \) vertices as \( P_{p,q} \). The density matrix \( \rho(G) \) of the graph \( G \) is given by

\[
\rho(G) = \frac{1}{2} \sum_{i=1}^{n/2} P \left[ \frac{1}{\sqrt{2}} (|i,j| - |i',j'|) \right].
\]

Let \( G \in P_{p,q} \). Let \( G^a \) be the graph with vertex set as \( V(G) \) and \( \{(i,j),(i',j')\} \in E(G^a) \) if and only if \( \{(i,j),(i',j')\} \in E(G) \). Let \( P_{p,q}^S \in P_{p,q} \). It can be easily shown that for any perfect matching \( G \) on \( n=pq \) vertices, \( G \in P_{p,q}^S \) if and only if \( \Delta(G) = \Delta(G^a) \). Following are the examples of “canonical” perfect entangling matchings.

(1) Crisscross: A crisscross \( C \) is given by

\[
C = \{(i_1,1),(i_1,2),(i_2,1),(i_2,2),\ldots\).
\]

(2) Tally mark: A tally mark \( T \) is given by \( T = \{(i_1,1):k = 1,2,\ldots,r'\} \cup \{(i_2,2):k = 1,2,\ldots,r''\} \) and \( E(T) = \{(i_1,1),(i_2,2),(i_1,1),(i_2,2),\ldots\} \)

\[
\{(i_1,1),(i_2,2)\}.
\]

(3) Crisscross: A crisscross \( C \) is given by

\[
C = \{(i_1,1),(i_1,2),(i_2,1),(i_2,2),\ldots\).
\]

(2) Tally mark: A tally mark \( T \) is given by \( T = \{(i_1,1):k = 1,2,\ldots,r'\} \cup \{(i_2,2):k = 1,2,\ldots,r''\} \) and \( E(T) = \{(i_1,1),(i_2,2),(i_1,1),(i_2,2),\ldots\} \)

\[
\{(i_1,1),(i_2,2)\}.
\]

(3) Crisscross: A crisscross \( C \) is given by

\[
C = \{(i_1,1),(i_1,2),(i_2,1),(i_2,2),\ldots\).
\]

(2) Tally mark: A tally mark \( T \) is given by \( T = \{(i_1,1):k = 1,2,\ldots,r'\} \cup \{(i_2,2):k = 1,2,\ldots,r''\} \) and \( E(T) = \{(i_1,1),(i_2,2),(i_1,1),(i_2,2),\ldots\} \)

\[
\{(i_1,1),(i_2,2)\}.
\]
It then follows that the two subsets \{i_1 : k = 1, 2, \ldots, q\} and \{j_1 : k = 1, 2, \ldots, q\} of \{1, 2, \ldots, p\} must be same. This is so because if some \(j_1 \notin \{i_1 : k = 1, 2, \ldots, q\}\), then vertex \((j_1, 1)\) of the (entangled) edge \([(i_1, 2), (j_1, 1)]\) in \(G_1\) will belong to \(V(G_1)\) [and hence, to \(V(G_1)\)]—a contradiction. Therefore, \(G_2\) (and, hence, \(G_4\)) is a perfect entangling matching on the set of \(2q\) vertices \((i, j)\), where \(i \in \{i_1, i_2, \ldots, i_q\}\) and \(j \in \{1, 2\}\). Note that this fact is true not only for \(n = 2p\) but for any general \(n = p' \cdot q'\), provided \(n\) is even [and so, for any \(G \in \mathcal{P}_{p' \cdot q'}\), \(G \in \mathcal{P}_{p' \cdot q'}^S\) if and only if \(\Delta(G) = \Delta(G^{I_{11}})\)].

Now, it is known that (see lemma 4.4 in [11]) any perfect entangling matching \(G'\) on \(n = 2p'\) vertices \(v_1' = (1, 1), v_2' = (1, 2), v_3' = (2, 1), v_4' = (2, 2), \ldots, v_{(2p'-1)}' = (p', 1), v_{2p'}' = (p', 2)\) can be transformed in to a “canonical” perfect entangling matching \(G_0\) on the same set of vertices by applying a suitable permutation on the first label of the vertices \(v_1', v_2', \ldots, v_{2p'}\) where, by “canonical” perfect entangling matching, we mean either (i) a crisscross, (ii) a tally mark, or (iii) a disjoint union of some tally marks and/or some crisscrosses (this kind of result is still lacking for a general \(G \in \mathcal{P}_{p' \cdot q'}\) and we do not know what should be the canonical form of such a \(G\). As \(p(G_0)\) is known to be separable in \(C_q^p \otimes C_q^p\) (according to lemma 4.5 in [11] together with the fact that the density matrix of a crisscross is always separable), therefore \(p(G')\) is separable in \(C_q^p \otimes C_q^p\).

Thus, it follows that \(p(G_2)\) is separable in \(C_q^p \otimes C_q^p\) (and hence, in \(C_q^p \otimes C_q^p\) as \(C_q^p\) is contained inside the orthonormal basis \(\{|i\} : l = 1, 2, \ldots, p, k = 1, 2, \ldots, q\}\) of \(C_q^p\)). Also \(p(G_1)\) is separable in \(C_q^p \otimes C_q^p\) as \(G_1\) consists of only unentangled edges of \(G\). Now \(p(G) = (1/p)(\rho(G) + q\rho(G_2))\) where \(p(G)\) is separable in \(C_q^p \otimes C_q^p\). □

During the proof of theorem 4, we have proved the following result.

**Corollary 1.** Let \(G\) be a perfect matching on \(n = p \cdot q\) vertices \(v_1 = (u_1, w_1), v_2 = (u_2, w_2), \ldots, v_{pq} = (u_{pq}, w_{pq})\) for which \(\Delta(G) = \Delta(G^{I_{pq}})\). Then \(G\) is a disjoint union of \(N\), the number of distinct matchings \(G_1, G_2, \ldots, G_N\) where \(G(i, j)\) is \(\{(u_{ij}, w_{ij}) : j = 1, 2, \ldots, p, i = 1, 2, \ldots, q\}\), \(\bigcup_{j=1}^{N} \{w_{ij}\} = \bigcup_{j=1}^{N} \{u_{ij}\}\) for every \(i, j, k\) such that \(u_{ij}, u_{ik} = \emptyset\) or \(w_{ij}, w_{ik} = \emptyset\) or both, and for each \(i \in \{1, 2, \ldots, N\}\), either \(G_i\) consists of only unentangled edges or only entangled edges, but not both.

Thus we see that, for any perfect matching \(G\), when the degree condition is satisfied, it is enough to study the separability of the density matrices of its pairwise disjoint entangled subgraphs (i.e., subgraphs each of whose edge is entangled), each of which is a perfect entangling matching on its own right (i.e., it is a perfect entangling matching on a set \(S\) of vertices taken from \(V(G)\)) such that all the elements of \(S\) can be labeled by two labels). See Fig. 2 for an illustration.

A speciality of the case \(n = p = 2\) is also reflected in the following lemma.

![FIG. 2. A perfect matching \(G\) on 16 vertices (1,1),(1,2),...,(4,4), for which the degree condition is satisfied. \(G\) is the disjoint union of the following four perfect matchings: (i) The unentangled graph: \(G_1 = (V(G_1), E(G_1)) = (\{(1, 1), (1, 2), (2, 1), (2, 2)\})\) and \(E(G_1) = \{(1, 1), (1, 2), (2, 1), (2, 2)\}\). (ii) The crisscross: \(G_2 = (V(G_2), E(G_2)) = \{(1, 1), (1, 2), (2, 1), (2, 2)\}\). (iii) The perfect entangling matching \(G_3 = (V(G_3), E(G_3)) = \{(1, 1), (1, 2), (2, 1), (2, 2)\}\). (iv) The unentangled graph: \(G_4 = (V(G_4), E(G_4)) = \{(1, 1), (1, 2), (2, 1), (2, 2)\}\).](image-url)
set, we still do not have any proof of separability of the corresponding density matrices. But for a particular class of perfect entangling matchings $G$ on $n = p(2r)$ vertices, for each of which the degree condition is satisfied, one can show that $\rho(G)$ is separable in $C_2^r \otimes C_2^r$.

Let $G \in \mathcal{P}_p(2r)$, where $G = \bigcup_{i=1}^r G_{i,j^i}$, with $V(G_{i,j^i}) = \{(a,j_i): a = 1,2,\ldots,p\} \cup \{(i,j_i):a = 1,2,\ldots,p\}$ and $E(G_{i,j^i}) = \{(a,j_i),(i^{(k)}_i,j_i): a = 1,2,\ldots,p\}$ such that for each $k \in \{1,2,\ldots,r\}$, (i) $i^{(k)}_i \in \{1,2,\ldots,p\}\{a\}$ for each $a \in \{1,2,\ldots,p\}$ and (ii) $j_k, l_k \in \{1,2,\ldots,2r\}$ with the properties that $j_k \neq l_k$, $j_k \neq j_{k'}$ (if $k \neq k'$) and $l_k \neq l_{k'}$ (if $k \neq k'$). Thus we see that for each $k \in \{1,2,\ldots,r\}$, $G_{i,j^i}$ is a perfect entangling matching on $2p$ vertices $(1,j_k), (1,l_k), (2,j_k), (2,l_k), \ldots, (p,j_k), (p,l_k)$ and with $p$ edges $\{(1,j_k),(i^{(k)}_k,l_k)\}$, $\{(2,j_k),(i^{(k)}_k,l_k)\}, \ldots, \{(p,j_k),(i^{(k)}_k,l_k)\}$. So, by lemma 4.4 of [11], $G_{i,j^i}$ can be transformed into a canonical perfect entangling matching on same set of vertices. And so $\rho(G_{i,j^i})$ is separable in $C_2^r \otimes C_2^r$ [and so, by theorem 2, $\Delta(G_{i,j^i}) = \Delta(G_{i,j^i}) = \Delta(G_{i,j^i})$. Therefore, $\rho(G) = \oplus_{i=1}^r \rho(G_{i,j^i})$ is separable in $C_2^r \otimes C_2^r$ and $\Delta(G) = \oplus_{i=1}^r \Delta(G_{i,j^i}) = \sum_{i=1}^r \Delta(G_{i,j^i}) = \Delta(G_{i,j^i})$.]

The set of all elements in $\mathcal{P}_p(2r)$, each of which is a disjoint union of exactly $r$ number of elements of $\mathcal{P}_p(2r)$, is denoted here by $\mathcal{E}_p(2r)$. Let $G \in \mathcal{E}_p(2r)$. Then, as described above, $G$ is a disjoint union of $r$ elements $G_{i,j^i_l}, G_{i,j^i_2}, \ldots, G_{i,j^i_r}$ of $\mathcal{P}_p(2r)$. Note that each element $G_{i,j^i_l}$ of $\mathcal{P}_p(2r)$ is a disjoint union of $N_k$ number of elements $G_{i,j^i_k}(L_{i,k})$ ($\in \mathcal{E}_{p}^{(L_{i,k})}$), $G_{i,j^i_k}(L_{i,k})$ ($\in \mathcal{E}_{p}^{(L_{i,k})}$), $G_{i,j^i_k}(L_{i,k})$ ($\in \mathcal{E}_{p}^{(L_{i,k})}$), and so we have $N = \sum_{i=1}^r N_k$. Now by using lemma 4.4 of [11], we have

$$\rho(G_{i,j^i_k}(L_{i,k})) = \frac{1}{L_{i,k}} \sum_{i=1}^{L_{i,k}} P \left( \frac{2\pi(i-1)!}{L_{i,k}} \right) \times U_{i,j_{i_k}}(i^{(k)}_{i_k}) \times |l_{i_k}\rangle \right) \right),$$

where $U_{i,j_{i_k}}$ is the permutation matrix corresponding to a permutation on the labels $a_{i_k}^{(1)}, a_{i_k}^{(2)}, \ldots, a_{i_k}^{(r)}$ for $i' \in \{1,2,\ldots,N_k\}$ and $k = 1,2,\ldots,r$. So we have

$$\rho(G_{i,j^i_k}(L_{i,k})) = \frac{1}{N_k} \sum_{i=1}^{N_k} \rho(G_{i,j^i_k}(L_{i,k})).$$

and, finally,

$$\rho(G) = \frac{1}{L_{i,k}} \sum_{i=1}^{L_{i,k}} \rho(G_{i,j^i_k}(L_{i,k})).$$

(2.14)

Note that the range of $\rho(G)$ (where $G \in \mathcal{E}_p(2r)$) will always contain at least $pr$ number of pairwise orthogonal product states: namely, the states

$$\frac{1}{L_{i,k}} \sum_{m=1}^{L_{i,k}} \exp \left( \frac{2\pi(i-1)!}{L_{i,k}} \right) U_{i,j_{i_k}}(i^{(k)}_{i_k}) \otimes \frac{1}{\sqrt{2}} \left[ |j_{i_k}\rangle - \exp \left( \frac{-2\pi \bar{l}_{i_k}}{L_{i,k}} \right) |l_{i_k}\rangle \right].$$

\begin{align*}
\text{FIG. 3. A perfect entangling matching} & \quad G \in \mathcal{P}_{p(2r)} (2,2) \text{ on the 24 vertices} \\
& \quad (1,1), (1,2), \ldots, (6,4), \text{ } G \text{ is a disjoint union of two perfect entangling matchings} \\
& \quad G_{13} \text{ and } G_{23} \text{ in } \mathcal{E}_{p(2r)}(2,2) \text{, where } V(G_{13}) = \{(i,j) | i = 1,2,\ldots,6 \cup ((i,3)|i=1,2,\ldots,6) \text{ and } V(G_{23}) = \{(i,2)|i=1,2,\ldots,6 \cup ((i,4)|i=1,2,\ldots,6) \}. \text{ So, } G \in \mathcal{E}_{p(2r)} \text{, it is a disjoint union of two perfect entangling matchings} G_{13} \text{ and } G_{23} \text{ in } \mathcal{E}_{p(2r)} \text{, as a disjoint union of perfect entangling matchings is possible (see Fig. 3 for an illustration). For each } i \in \{1,2,\ldots,N_k\} \text{, we must have } V(G_{i,j^i_k}(L_{i,k})) = \{(a^{(i)}_{i_k},j_{i_k})|m = 1,2,\ldots,L_{i,k} \cup \{a^{(i)}_{i_k},l_{i_k})|m = 1,2,\ldots,L_{i,k} \}, \text{ where } a^{(i)}_{i_k} \text{ is the permutation matrix corresponding to a permutation on the labels } a_{i_k}^{(1)}, a_{i_k}^{(2)}, a_{i_k}^{(3)}, \ldots, a_{i_k}^{(r)} \text{ for } i' \in \{1,2,\ldots,N_k\} \text{ and } k = 1,2,\ldots,r. \text{ So we have } \rho(G_{i,j^i_k}(L_{i,k})) = \frac{1}{L_{i,k}} \sum_{i=1}^{L_{i,k}} \rho(G_{i,j^i_k}(L_{i,k})). \text{ and, finally, } \rho(G) = \frac{1}{L_{i,k}} \sum_{i=1}^{L_{i,k}} \rho(G_{i,j^i_k}(L_{i,k})). \text{ Note that the range of } \rho(G) \text{ (where } G \in \mathcal{E}_p(2r) \text{) will always contain at least } pr \text{ number of pairwise orthogonal product states: namely, the states } \frac{1}{L_{i,k}} \sum_{m=1}^{L_{i,k}} \exp \left( \frac{2\pi(i-1)!}{L_{i,k}} \right) U_{i,j_{i_k}}(i^{(k)}_{i_k}) \otimes \frac{1}{\sqrt{2}} \left[ |j_{i_k}\rangle - \exp \left( \frac{-2\pi \bar{l}_{i_k}}{L_{i,k}} \right) |l_{i_k}\rangle \right]. \text{ where } \sum_{i=1}^{N_k} L_{i,k} = p \text{ and } k = 1,2,\ldots,r. \text{ The range of } \rho(G) \text{ can also contain some other (possibly infinite in number) product states if either } (i) \text{ } L_{i,k} = L_{i,k} \text{ for different } i, i' \in \{1,2,\ldots,N_k\} \text{ or } (ii) \{a^{(i)}_{i_k}, a^{(i)}_{i_k}, \ldots, a^{(k)}_{i_k}\} = \{a^{(i')}_{i_k}, a^{(i')}_{i_k}, \ldots, a^{(k')}_{i_k}\} \text{ for different } k, k' \in \{1,2,\ldots,r\} \text{ (but for same } i). \text{ All the above-
mentioned crisscross or tally mark. As crisscrosses or tally marks always contain a crisscross or tally mark. Let \( H \in \mathcal{P}^S_{p(r^2)} \backslash \mathcal{E}_{p(r^2)} \). Is \( \rho(H) \) a separable state in \( \mathcal{C}_p^r \otimes \mathcal{C}_p^r \)? In order to answer this question, we need to see whether there is any product state of \( \mathcal{C}_p^r \otimes \mathcal{C}_p^r \) within the range \( \mathcal{R}_H \) of \( \rho(H) \). Also we consider here the density matrix \( \rho(H) \) is an identity matrix. Let \( \mathcal{R}_H \) be the range of \( \rho(H) \). We have the following conjecture.

Conjecture 2. Let \( H \in \mathcal{P}^S_{p(r^2)} \backslash \mathcal{E}_{p(r^2)} \) such that \( H \) neither contains any crisscross nor any tally mark. Then the range \( \mathcal{R}_H \) of \( \rho(H) \) contains exactly \( pr \) number of product states \( \{|i\rangle \otimes |j\rangle, \{k\rangle \otimes |l\rangle, \ldots, \{p\rangle \otimes |q\rangle\} \}\) for any \( p \neq q \) and \( r \), provided that \( \mathcal{R}_H \) contains a one-dimensional subspace of \( \mathcal{C}_p^r \otimes \mathcal{C}_p^r \). Moreover, (i) all these product states are pairwise orthogonal, (ii) all the states \( \{|i\rangle, \{j\rangle, \ldots, \{p\rangle\} \} \) are different but one can always have at least one class of exactly \( 2r \) of them all of which are pairwise orthogonal, (iii) all the states \( \{|i\rangle \otimes |j\rangle, \{k\rangle \otimes |l\rangle, \ldots, \{p\rangle \otimes |q\rangle\} \} \) are reliably distinguishable by LOCC.

The validity of conjecture 2 would directly show that for any \( H \in \mathcal{P}^S_{p(r^2)} \backslash \mathcal{E}_{p(r^2)} \), which neither contains any crisscross nor any tally mark, \( \rho(H) \) is a separable state in \( \mathcal{C}_p^r \otimes \mathcal{C}_p^r \). If an \( H \in \mathcal{P}^S_{p(r^2)} \backslash \mathcal{E}_{p(r^2)} \) contains some crisscroses and/or tally marks, the remaining part of \( H \) (eliminating out all these crisscroses, tally marks) will be again an element of \( \mathcal{P}^S_{p(r')} \backslash \mathcal{E}_{p(r')} \), for some \( p' \leq p \) and \( r' \leq r \), such that this new graph does not contain any crisscross or tally mark. As crisscrosses or tally marks always form separable density matrices, therefore we see that for any \( H \in \mathcal{P}^S_{p(r^2)} \backslash \mathcal{E}_{p(r^2)} \), \( \rho(H) \) is separable in \( \mathcal{C}_p^r \otimes \mathcal{C}_p^r \), provided the above-mentioned conjecture is true. Note that the validity of conjecture 1 automatically implies that for any \( G \in \mathcal{P}^S_{p(r^2)} \), \( \rho(G) \) is separable if \( G \in \mathcal{P}^S_{p(r^2)} \backslash \mathcal{E}_{p(r^2)} \). However, the statement in conjecture 2 is much stronger than just saying that \( \rho(G) \) is separable if \( G \in \mathcal{P}^S_{p(r^2)} \backslash \mathcal{E}_{p(r^2)} \).

D. Proof of theorem 5

Let \( \rho \) be a circulant density matrix of dimension \( n = pq \). As we already mentioned in the Introduction, we can write \( \rho = \sum_{g \in \mathbb{Z}_n} f(g) \sigma(g) \) where \( f \) is a complex-valued function. Obviously, there will be some constraints imposed by the fact that \( \rho \) is positive semidefinite and Hermitian. It is well known that \( \rho \) is diagonalized by the Fourier transform \( \mathcal{F}(\mathbb{Z}_n) \) over \( \mathbb{Z}_n \) [17]: \( \rho = \mathcal{F}(\mathbb{Z}_n) \mathcal{F}(\mathbb{Z}_n)^* \). The eigenvectors of \( \rho \) are then the columns of \( \mathcal{F}(\mathbb{Z}_n)^* \). We prove the theorem in two steps: (1) we prove that \( |\lambda\rangle \) is an eigenvector of \( \rho \), where \( |\lambda\rangle = |a\rangle \otimes |b\rangle \), for any \( a \in \mathcal{C}_p^r \) and \( b \in \mathcal{C}_p^r \), and \( \mathcal{C}_p^r \) is an n-by-n matrix which is diagonalized by a unitary matrix \( U \). We take \( n = pq \), and thus \( \mathcal{F}(\mathbb{Z}_n) = \text{diag}(\lambda_1, \ldots, \lambda_n) \), with respect to the standard orthonormal basis \( \{ |\psi_1\rangle, \ldots, |\psi_n\rangle \} \). Thus \( \rho = \sum_{i=1}^n \lambda_i |\psi_i\rangle \langle \psi_i| \). The unitary matrix \( U \) is the Fourier transform over \( \mathbb{Z}_n \). We can see that

\[
\rho = \sum_{i=1}^n \lambda_i |\psi_i\rangle \langle \psi_i| = \sum_{i=1}^n \lambda_i \left( \frac{1}{n} \sum_{l=0}^{n-1} e^{-2\pi i (j-1)l/n} |\psi_{i,l}\rangle \langle \psi_{i,l}| \right)
\]

for any \( \lambda_j \geq 0 \) for \( j = 1, \ldots, n \).

(2) The general form of a circulant density matrix is

\[
\rho = \begin{bmatrix}
\lambda_1 & \lambda_2 & \cdots & \lambda_n \\
\lambda_2 & \lambda_3 & \cdots & \lambda_1 \\
\vdots & \vdots & \ddots & \vdots \\
\lambda_n & \lambda_1 & \cdots & \lambda_{n-1}
\end{bmatrix}
\]

Since the matrix is symmetric, we have...
Now, consider the block \( A \) and define
\[
a_1 = a_{11}, \quad a_2 = a_{12}, \quad a_3 = a_{13}, \ldots, \quad a_1 = a_{n+1}.
\]
(2.15)
Consider \( \rho \) as a block matrix with \( p^2 \) blocks, each block being a \( q \times q \) matrix:
\[
\rho = \begin{bmatrix}
A_{1,1} & A_{1,2} & \cdots & A_{1,n} \\
A_{2,1} & A_{2,2} & \cdots & A_{2,n} \\
& \ddots & \ddots & \ddots \\
A_{n,1} & A_{n,2} & \cdots & A_{n,n}
\end{bmatrix}.
\]
Consider the block \( A_{1,m+1} \). Then \( [A_{1,m+1}]_{1,1} = a_{mq+1} \). Let \( l = mq+1 \). Then,
\[
A_{1,m+1} = \begin{bmatrix}
a_1 & a_{1+l} & \cdots & a_{1+q-1} \\
a_{1+l} & a_1 & \cdots & a_{1+q-2} \\
& \ddots & \ddots & \ddots \\
a_{1+q-1} & \cdots & \cdots & a_l
\end{bmatrix}.
\]
Now, consider the block \( A_{1,p-m+1} \). Then \( [A_{1,p-m+1}]_{1,1} = a_{n+1} \). Let \( l = n+1 \). Then,
\[
A_{1,n-m+1} = \begin{bmatrix}
a_{n+1} & a_{n+1+q} & \cdots & a_{n+1+q-1} \\
a_{n+1+q} & a_{n+1} & \cdots & a_{n+1+q-2} \\
& \ddots & \ddots & \ddots \\
a_{n+1+q-1} & \cdots & \cdots & a_{n+1+q-3}
\end{bmatrix}
\]
Applying the condition expressed in Eq. (2.15), one can verify that
\[
A_{1,m+1} = A^\dagger_{1,n-m+1}.
\]
This argument extends to all blocks of the \( i \) th block row of \( \rho \). For example, the first block row of \( \rho \) is then of the form
\[
A_{1,1} = \begin{bmatrix}
A_{1,1} & A_{1,2} & \cdots & A_{1,n} \\
& \ddots & \ddots & \ddots \\
& & \ddots & \ddots \\
& & & \ddots & \ddots \\
& & & & \ddots & \ddots \\
& & & & & \ddots & \ddots \\
& & & & & & \ddots & \ddots \\
& & & & & & & \ddots & \ddots \\
& & & & & & & & \ddots & \ddots \\
& & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & & & & & & & & \ddots & \ddots \\
\end{bmatrix}
\]
if \( p \) is even and
\[
A_{1,1} = \begin{bmatrix}
A_{1,1} & A_{1,2} & \cdots & A_{1,n} \\
& \ddots & \ddots & \ddots \\
& & \ddots & \ddots \\
& & & \ddots & \ddots \\
& & & & \ddots & \ddots \\
& & & & & \ddots & \ddots \\
& & & & & & \ddots & \ddots \\
& & & & & & & \ddots & \ddots \\
& & & & & & & & \ddots & \ddots \\
& & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & & & & & & \ddots & \ddots \\
& & & & & & & & & & & & & & & & & & & & \ddots & \ddots \\
\end{bmatrix}
\]
if \( p \) is odd. It is then clear that \( \Delta(\rho) = \Delta(\rho^T) \); that is, the row sums of \( \rho \) are invariant under the partial transpose. It should be noted here that each element of \( \Delta(\rho) \) [as well as of \( \Delta(\rho^T) \)] is real due to Eq. (2.15).

The same reasoning applies to the second part of the theorem. The only difference is that \( \rho = \sum_{g \in \Sigma(G)} \sigma(g) \) is diagonalized by the Hadamard matrices of Sylvester type, \( H^p = H^p \otimes H \), where \( H \) is the \( 2 \times 2 \) Hadamard matrix [16].

### III. OPEN PROBLEMS

In this paper we have studied the separability of a class of states associated with the combinatorial Laplacians of graphs. The graphs for these states compactly encode information about their bipartite entanglement. We have shown that invariance of the degree matrices under partial transposition gives, in many cases, significant information about the separability of the states. Now the Peres-Horodecki partial transposition condition (known as the PPT criterion) is only a necessary condition (in general) for separability of any bipartite density matrices [7,8]. In fact, all the practical separability conditions, available so far, are either necessary or sufficient for general bipartite density matrices (see, for example, [10]). The degree condition, described in this paper, is of course weaker than the PPT criterion, as not all bipartite density matrices (not even the separable ones) can be described as density matrices generated from graphs. Nevertheless the validity of conjecture 1 (together with theorem 2) would imply that the degree condition is both necessary as well as sufficient for some particular classes of bipartite density matrices irrespective of the dimension of the system. In the quest for resolving the separability problem with the help of practical necessarily sufficient conditions (i.e., conditions, each of which is both necessary as well as sufficient), one possible way would be to find out the set of all possible independent but practical necessarily sufficient conditions each of which decides the separability problem of a maximal set of bipartite density matrices in such a way that the collection of these later sets would comprise the entire set of bipartite density matrices. The present work is one step forward in that direction. The following points are open for further investigation.

#### A. Partial transposition as a local permutation

It is not difficult to see that for any graph on \( n = p \cdot q \) vertices \( v_1 = u_1 w_1, \ldots, v_{pq} = u_p w_q \), if \( \Delta(G) = \Delta(G^F) \), then there is a permutation matrix \( P \) on the labels \( w_1, \ldots, w_q \) such that
\[
\Delta(G^F) = (I \otimes P) \Delta(G)(I \otimes P^{-1}),
\]
\[
M(G^F) = (I \otimes P) M(G)(I \otimes P^{-1}).
\]
This says that if the degree condition is satisfied, then the operation of partial transposition is nothing but a local permutation. Note that this is, in general, false for the case of any given bipartite separable density matrix. The relation between separability of density matrices of graphs and isomorphism remains to be studied.

#### B. Structure of bipartite Hilbert spaces

The validity of of conjecture 6 can be traced back to basic problems in the structure of any bipartite Hilbert space.
Given a subspace $S$ of dimension $d$ of $\mathcal{H}$, what are the necessary and sufficient conditions under which at least one of the following situations hold good?

(i) $S$ contains at least one linearly independent product state.

(ii) $S$ contains only $d'$ linearly independent product states, where $d' < d$.

(iii) $S$ contains more than $d$ product states (in which case they must be linearly dependent).

(iv) $S$ contains exactly $d$ linearly independent product states and these are pairwise orthogonal.

(v) $S$ contains only $d'$, where $d' \leq d$, pairwise orthogonal product states that one can extend to a full orthogonal product basis of $\mathcal{H}$, etc.

C. Multiparty entanglement

As a generalization of our result to density matrices of graphs having multiple labels on their vertices, we expect that if $G$ is a graph on $n=p_1 p_2 \cdots p_m$ vertices,

$$v_i = u^{(s_i^{(1)} u_2^{(s_i^{(2)})} \cdots u_m^{(s_i^{(m)})}}, \text{ where } s_i^{(j)} \in \{1, \ldots, p_j\}$$

for $j = 1, \ldots, m$ and $i = 1, \ldots, n$,

then $\rho(G)$ is a separable density matrix in $(\mathbb{C}^{p_1} \otimes \mathbb{C}^{p_2} \otimes \cdots \otimes \mathbb{C}^{p_m})$ if and only if $\Delta(G) = \Delta(G^T)$.

Moreover, we expect that $\rho(G)$ is a completely separable density matrix in $(\mathbb{C}^{p_1} \otimes \mathbb{C}^{p_2} \otimes \cdots \otimes \mathbb{C}^{p_m})$ if and only if $\Delta(G) = \Delta(G^T)$ for $j = 1, \ldots, m$ [18].
